ORTHOGONAL DECOMPOSITION OF FINITE POPULATION STATISTICS AND ITS APPLICATIONS TO DISTRIBUTIONAL ASYMPTOTICS

M. BLOZNELIS\textsuperscript{1,3} AND F. GÖTZE\textsuperscript{2}

\textsuperscript{1}Vilnius University and Institute of Mathematics and Informatics, \textsuperscript{2}Bielefeld University

Abstract. We study orthogonal decomposition of symmetric statistics based on samples drawn without replacement from finite populations. Several applications to finite population statistics are given: we establish one term Edgeworth expansions for general asymptotically normal symmetric statistics, prove Efron–Stein inequality and consistency of the jackknife estimator of variance. Our expansions provide second order a.s. approximations to Wu’s (1990) jackknife histogram.

1. Introduction

Orthogonal decomposition of statistics were introduced by Hoeffding (1948) in his proof of the asymptotic normality of $U$–statistics. Since then the orthogonal decomposition (called also ANOVA decomposition or Hoeffding’s decomposition) became an indispensable tool of analysis of distributional properties of statistics based on independent observations. In particular it plays a crucial role in the analysis of variance components (Efron and Stein 1981, Karlin and Rinott 1982, Vitale 1992) and provides a natural framework for the first and the second order asymptotics of statistics (Hajek 1968, Rubin and Vitale 1980, van Zwet 1984, Bentkus, Götze and van Zwet 1997).

We study orthogonal decomposition of statistics based on \textit{samples drawn without replacement} from finite populations. For simplicity we consider the case of simple random samples. We start with an overview of the orthogonal decomposition of general symmetric statistics based on simple random samples, see Section 2 below.

\textsuperscript{1}Research supported by Alexander von Humboldt Foundation
Here we also provide bounds for the remainders of the approximation of statistics by a fixed number, say two or three, of terms of the Hoeffding decomposition. Orthogonal decompositions of finite population $U$-statistics of fixed degree $k$ were used first in Zhao and Chen (1990) without providing uniform estimates for the remainders as $k$ increases together with the number of observations.

In Section 3 some brief applications are given. Here we prove the consistency of the jackknife variance estimator for symmetric statistics based on samples drawn without replacement, the finite population Efron–Stein inequality and discuss second order approximations to the distribution of jackknife histogram (Shao 1989, Wu 1990, Booth and Hall 1993) and sub-sampling (Politis and Romano 1994, Bickel, Götze and van Zwet 1997, Bertail 1997). In Section 4 the Hoeffding decomposition is used to establish asymptotic expansions for distribution functions of general symmetric finite population statistics.

2. Hoeffding’s decomposition

Let $T = t(X_1, \ldots, X_n)$ denote a statistic based on simple random sample $X_1, \ldots, X_n$ drawn without replacement from a finite population $X = \{x_1, \ldots, x_N\}$ consisting of $N$ units. Clearly, $n < N$. We shall assume that the function $t$ is invariant under permutations of its arguments. Therefore, $T$ is a symmetric statistic.

The Hoeffding decomposition

(2.1) \[ T = \mathbf{E} T + \sum_{1 \leq i \leq n} g_1(X_i) + \sum_{1 \leq i < j \leq n} g_2(X_i, X_j) + \ldots \]

represents $T$ by the sum of $n$ mutually uncorrelated $U$-statistics of increasing order. Here $g_k, k = 1, 2, \ldots, n$, denote symmetric kernels, which satisfy

(2.2) \[ \mathbf{E} (g_k(X_{i_1}, \ldots, X_{i_k}) \mid X_{j_1}, \ldots, X_{j_r}) = 0, \]

for every $1 \leq i_1 < \cdots < i_k \leq n$ and $1 \leq j_1 < \cdots < j_r \leq n$ such that $r < k$. It is easy to verify that such decomposition is unique.

The functions $g_k, k = 1, \ldots, n$, are linear combinations of conditional expectations

\[ h_j(x_{i_1}, \ldots, x_{i_j}) = \mathbf{E} (T - \mathbf{E} T \mid X_1 = x_{i_1}, \ldots, X_j = x_{i_j}). \]

We show in Appendix below that

(2.3) \[ g_k(x_1, \ldots, x_k) = d_{n,k} \sum_{j=1}^{k} M_{k,j} \sum_{1 \leq i_1 < \cdots < i_j \leq k} h_j(x_{i_1}, \ldots, x_{i_j}). \]
Here, for $k = 2, 3, \ldots, n$ the coefficients

$$d_{k,j} = \prod_{r=j}^{k-1} \frac{N-r}{N-r-j}, \quad 1 \leq j \leq \min\{k-1, N-k\}. \quad (2.4)$$

In the case where $2k > N + 1$ we put $d_{k,j} = 0$ for $N - k < j \leq k - 1$. Finally, we write $d_{n,n} = 1$, for $2n \leq N + 1$ and $d_{n,n} = 0$, for $2n > N + 1$. Furthermore, the coefficients $M_{k,j}$, for $k$ satisfying the inequality $2k \leq N + 1$, are given by the recursive relation

$$M_{k,j} = -\sum_{i=j}^{k-1} d_{k,i} M_{i,j} \binom{k-j}{i-j}, \quad 1 \leq j \leq k - 1,$$

and we put $M_{k,k} = 1$. For $2k > N + 1$ we write $M_{k,j} = 0$.

A simple calculation gives

$$g_1(x) = \frac{N-1}{N-n} h_1(x),$$

$$g_2(x, y) = \frac{N-2}{N-n} \frac{N-3}{N-n-1} \left( h_2(x, y) - \frac{N-1}{N-2} (h_1(x) + h_1(y)) \right).$$

Let $U_j$, $1 \leq j \leq n$ denote the $j$–th sum in (2.1),

$$U_j = U_j(T) = \sum_{1 \leq i_1 < \cdots < i_j \leq n} g_j(X_{i_1}, \ldots, X_{i_j}).$$

Clearly, (2.2) implies $\mathbf{E} U_k U_r = 0$, for $k \neq r$. That is, the $U$-statistics of the decomposition (2.1) are mutually uncorrelated. Note, that in contrary to the i.i.d. case, the random variables $g_j(X_{i_1}, \ldots, X_{i_j})$ and $g_j(X_{k_1}, \ldots, X_{k_j})$ are not uncorrelated. Indeed, for $m$ denoting the number of elements of the intersection $\{i_1, \ldots, i_j\} \cap \{k_1, \ldots, k_j\}$ we have

$$s_{j,m} := \mathbf{E} g_j(X_{i_1}, \ldots, X_{i_j}) g_j(X_{k_1}, \ldots, X_{k_j}) = \frac{(-1)^{j-m}}{N-j} \sigma_j^2. \quad (2.5)$$

Here we denote $\sigma_j^2 = \mathbf{E} g_j^2(X_{i_1}, \ldots, X_{i_j})$. Invoking a simple combinatorial argument we evaluate the variances

$$\text{Var} U_j = \frac{n}{j} \frac{N-n}{N-j} \sigma_j^2 \quad \text{and} \quad \text{Var} T = \sum_{j=1}^{n} \frac{n}{j} \frac{N-n}{N-j} \sigma_j^2. \quad (2.6)$$
The formulas (2.5) and (2.6) have been used in Zhao and Chen (1990) for U-statistics of fixed degree \( k \). For convenience, we include the proof of (2.5) and (2.6), see Lemmas 1 and 2 in Appendix below.

Here we shall develop several consequences of (2.3) and (2.6) which are new and have important applications. It follows from (2.3) and (2.6) that for \( j > N - n \) we have \( U_j \equiv 0 \). That is, the decomposition (2.1) reduces to

\[
T = E T + U_1 + \cdots + U_{n_*}, \quad n_* = \min\{n, N - n\}.
\]

Moreover, (2.2) entails the duality property, formulated in Proposition 1 below.

Let \((X_1, \ldots, X_N)\) denote a random permutation of the ordered set \((x_1, \ldots, x_N)\) which is uniformly distributed over the class of permutations. Then the first \( n \) observations \( X_1, \ldots, X_n \) represent a simple random sample from \( \mathcal{X} \). For \( j = 1, \ldots, N - n \) denote \( X'_j = X_{n+j} \).

**Proposition 1.** For \( j \leq n_* \) we have

\[
U_j \equiv U'_j, \quad \text{where} \quad U'_j = (-1)^j \sum_{1 \leq i_1 < \cdots < i_j \leq N - n} g_j(X'_{i_1}, \ldots, X'_{i_j}).
\]

Therefore, \( T \equiv T' \), where \( T' = E T + U'_1 + \cdots + U'_{n_*} \).

The proposition says that, in a sense \( T \) is a function of \( n_* \) random variables. In particular, if \( n > N/2 \) one may replace the statistic by a \( U \)-statistic based on \( n_* < N/2 \) observations.

**Proof of Proposition 1.** For the linear statistic \( U_1 \) the identity (2.8) is a consequence of \( E U_1 = 0 \). For \( j = 2, \ldots, n_* \), this identity follows from (2.2).

One may view the decomposition (2.1) as a stochastic expansion of the statistic \( T \). Indeed, for a number of statistics the first few terms of the decomposition provide a sufficiently precise approximations. To bound the errors of such approximations we introduce appropriate smoothness conditions.

Denote

\[
D^j T = t(X_1, \ldots, X_n) - t(X_1, \ldots, X_{j-1}, X_{j+1}, \ldots, X_n, X'_j), \quad X'_j = X_{n+j}.
\]

A higher order difference operations are defined recursively

\[
D^{j_1,j_2} T = D^{j_2} (D^{j_1} T), \quad D^{j_1,j_2,j_3} T = D^{j_3} (D^{j_2} (D^{j_1} T)), \ldots.
\]

They are symmetric, i.e., \( D^{j_1,j_2} T = D^{j_2,j_1} T \), etc. Given \( k < n_* \) write

\[
\delta_j = \delta_j(T) = E \left( n_*^{-1} \mathbb{D}_j T \right)^2, \quad \mathbb{D}_j T = D^{1,2,\ldots,j} T, \quad 1 \leq j \leq k.
\]

In Examples 1 and 2 below we estimate the moments \( \delta_j \) for \( U \) statistics and smooth functions of sample means.

**Theorem 1.** For \( 1 \leq k < n_* \), we have

\[
T = E T + U_1 + \cdots + U_k + R_k, \quad \text{with} \quad E R_k^2 \leq n_*^{-(k-1)} \delta_{k+1}.
\]

The proof of Theorem 1 is given in the Appendix.
3. Applications

Jackknife estimator of variance. The Quenouille–Tukey jackknife estimator of variance is a symmetric statistic of observations $X_1, \ldots, X_{n+1}$,

$$\sigma_J^2 = \sigma_J^2(T) = \frac{1}{n+1} \sum_{j=1}^{n+1} (T(j) - \bar{T})^2,$$

$$\bar{T} = \frac{1}{n+1} \sum_{j=1}^{n+1} T(j),$$

where we write $T(j) = t(X_1, \ldots, X_{j-1}, X_{j+1}, \ldots, X_n, X_{n+1})$.

In the case of independent and identically distributed observations the jackknife estimator of variance is asymptotically consistent if the underlying statistic is sufficiently smooth, see e.g., Miller (1974), Parr (1985) and Shao and Wu (1989) where in the later paper several smoothness conditions are discussed.

Here we consider statistics based on samples drawn without replacement. Let $X_1, \ldots, X_n$ be a simple random sample drawn without replacement from the population $\mathcal{X} = \{x_1, \ldots, x_N\}$. The jackknife variance estimator for statistic $T = t(X_1, \ldots, X_n)$ is defined by

$$\sigma_{FJ}^2 = \sigma_{FJ}^2(T) = q\sigma_J^2(T), \quad \text{where} \quad q = (N-n)/N.$$

Note that $\sigma_{FJ}^2(T)$ is a symmetric statistic of the sample $X_1, \ldots, X_{n+1}$ drawn without replacement from the population $\mathcal{X}$. For a linear statistic $T = ET + \sum_{i=1}^n g_1(X_i)$ it is easy to show that $E\sigma_{FJ}^2(T) = \text{Var} T$.

Our first application of the orthogonal decomposition (2.1) is the finite population Efron–Stein inequality: for arbitrary symmetric finite population statistic $T = t(X_1, \ldots, X_n)$ we have

$$(3.1) \quad E\sigma_{FJ}^2(T) \geq \text{Var} T.$$

That is, the jackknife variance estimator tends to be biased upwards. In the i.i.d. case the Efron–Stein inequality was proved by Efron and Stein (1981). The proof of (3.1) is given in the Appendix.

Another application of (2.1) is a general consistency result for the estimator $\sigma_{FJ}^2$. Assuming that $n$ and $N \to \infty$ we prove the consistency of $\sigma_{FJ}^2$ for asymptotically linear symmetric finite population statistics. In order to formulate the consistency result we consider a sequence of statistics $T_n = t_n(X_1, \ldots, X_n)$. That is, we show that for every $\varepsilon > 0$

$$(3.2) \quad P\{|\sigma_{FJ}^2(T_n) - \text{Var} T_n| > \varepsilon\} = o(1) \quad \text{as} \quad n, N \to \infty.$$

Let $T_{i,n}$ denote the summand $g_1(X_i)$ of the linear part of decomposition (2.1) for the statistic $T_n$. 
Proposition 2. Assume that \( N \) and \( n_* = \min\{n, N - n\} \to \infty \). Assume that (i) for some \( 0 < c_1 < c_2 < \infty \), we have \( c_1 \leq \text{Var} T_n \leq c_2 \) and \( \delta_2(T_n) = o(1) \); (ii) for every \( \varepsilon > 0 \),

\[
(3.3) \quad n_* \mathbb{E} T^2_{1,n} \mathbb{I}_{T^2_{1,n} > \varepsilon} = o(1).
\]

Then (3.2) holds.

The proof of Proposition 2 is given in the Appendix.

Recall that \( \delta_2(T_n) = n^2_* \mathbb{E} \left( D^2 T_n \right) \), where \( D^2 T_n = t_n(X_1, \ldots, X_n) - t_n(X_2, \ldots, X_n, X_{n+1}) - t_n(X_1, X_3, \ldots, X_n, X_{n+2}) + t_n(X_3, \ldots, X_{n+2}). \)

Note that the condition (i) implies that \( T_n \) is asymptotically linear as \( n_* \to \infty \).

That is,

\[
(3.4) \quad T_n = \mathbb{E} T_n + \sum_{i=1}^{n} T_{i,n} + o_P(1), \quad \text{with} \quad \text{Var} \left( \sum_{i=1}^{n} T_{i,n} \right) \geq c_1 - o(1).
\]

Here \( \mathbb{E} T_n + \sum_{i=1}^{n} T_{i,n} \) denotes the linear part of the decomposition (2.1) of \( T_n \). Indeed, by (2.1), we have \( T_n = \mathbb{E} T_n + \sum_{i=1}^{n} T_{i,n} + r_n \), where the remainder \( r_n \) and the linear part are uncorrelated. The condition \( \delta_2(T_n) = o(1) \) implies the bound \( \mathbb{E} r^2_n = o(1) \), see Theorem 1. Therefore, (3.4) follows. Note that the uniform integrability condition (3.3) can be replaced by a more restrictive moment condition \( \limsup_n \mathbb{E} \left( T^2_{1,n} n_* \right)^{1+\delta} < \infty \), for some \( \delta > 0 \).

Sub-sampling. Let \( Y_1, \ldots, Y_n \) be independent observations from a probability distribution \( P \). Let \( \theta_n = \theta_n(Y_1, \ldots, Y_n) \) be an estimator of a real–valued parameter \( \theta = \theta(P) \). In order to make inferences about \( \theta \) one estimates the distribution of \( \theta_n - \theta \). Assuming that the distribution \( K_n \) of \( \tau_n(\theta_n - \theta) \) converges weakly to a limit law Politis and Romano (1994) showed that the conditional distribution function

\[
\hat{K}_m(x) = \mathbb{P}\{ \tau_m(\theta_m(X_1, \ldots, X_m) - \theta_n) \leq x \mid Y_1, \ldots, Y_n \}
\]

estimates the true distribution function \( K_n(x) = \mathbb{P}\{ \tau_n(\theta_n - \theta) \leq x \} \) consistently as \( n, m \to \infty \) so that \( m/n \to 0 \) and \( \tau_m/\tau_n \to 0 \). Here \( \tau_n \) denotes a non-random sequence of normalizing constants and \( X_1, \ldots, X_m \) denotes a random sample drawn without replacement from \( \{Y_1, \ldots, Y_n\} \). Assuming in addition that \( K_n(x) \) admits an Edgeworth expansion, Bertail (1997) showed that \( \hat{K}_m(x) \) admits a corresponding stochastic expansion. The proofs of Politis and Romano (1994) and Bertail
(1997) exploit the $U$–statistic structure of the conditional distribution function $\hat{K}_m(x)$ and rely on the law of large numbers for $U$–statistics.

Another way to construct higher order approximations to $\hat{K}_m(x)$ is based on conditional asymptotic expansions given $\{Y_1, \ldots, Y_n\}$. Let $v_m = v_m(Y_1, \ldots, Y_n)$ (respectively $e_m = e_m(Y_1, \ldots, Y_n)$) denote the conditional variance (respectively the mean value) of $\tau_m(\theta_m(X_1, \ldots, X_m) - \theta_n)$, given $Y_1, \ldots, Y_n$. Theorem 2 below provides the conditional asymptotic expansion

\[
\hat{K}_m(x v_m + e_m) = \Phi(x) - \hat{q}_m(x)\Phi^{(3)}(x)(m(1 - m/n))^{1/2} + O(m^{-1})
\]

almost surely as $m_* = \min\{m, n - m\} \to \infty$ and $n \to \infty$. An explicit formula for the first term of the expansion $\hat{q}_m(x)$ is provided in Section 4 below.

Wu (1990) used one term asymptotic expansion of finite population Studentized mean due to Babu and Singh (1985) to construct a second order approximation like (3.5) to the jackknife histogram of Studentized mean. Clearly, (3.5) provides such approximations with remainder $O(m^{-1})$ for a broad class of asymptotically linear statistics, see also Bickel, Götze and van Zwet (1997) for other possible applications of (3.5).

Let us mention that for some classes of statistics the order of the approximation of $\hat{K}_m(x)$ can be further improved by using Richardson extrapolation, see Bickel and Yahav (1988), Booth and Hall (1993), Bertail (1997).

Finally, we discuss applications to resampling of finite population statistics. Using orthogonal decomposition of Section 2 and Edgeworth expansions of Section 4 one can extend i.i.d. results of Putter and van Zwet (1998) on empirical Edgeworth expansions to samples drawn without replacement. This question is addressed in Bloznelis (2000). Furthermore, orthogonal decomposition of Section 2 and expansions of Section 4 below could be extended to stratified sampling without replacement models and applied to resampling schemes like finite population bootstrap (Gross (1980), Bickel and Freedman (1984), Chao and Lo (1985), Babu and Singh (1985), Chen and Sitter (1993), Booth, Butler and Hall (1994), Helmers and Wegkamp (1998)) and its modifications.

4. Stochastic and asymptotic expansions

We shall apply (2.9) to study the asymptotics of the distribution of $T$.

When speaking about the finite population asymptotics we assume that we have a sequence of populations $\mathcal{X}_r = \{x_{r,1}, \ldots, x_{r,N_r}\}$, with $N_r \to \infty$ as $r \to \infty$, and a sequence of symmetric statistics $T_r = t_r(X_{r,1}, \ldots, X_{r,n_r})$, based on samples $X_{r,1}, \ldots, X_{r,n_r}$ drawn without replacement from $\mathcal{X}_r$. We shall assume that the variances $\tilde{\sigma}_r^2 = \text{Var} T_r$ remain bounded away from zero as $r \to \infty$. In order to keep the notation simple we drop the subscript $r$ in what follows.
In typical situations ($U$–statistics, smooth functions of sample means, Student’s $t$ and many others) we have $U_j = O_P(n_*^{(1-j)/2})$, for $j = 1, \ldots, k$, and

$$\delta_{k+1} = O(n_*^{-1}) \quad \text{as} \quad n_*, N \to \infty,$$

for some $k$. Clearly, (4.1) is a smoothness condition. It implies the validity of the stochastic expansion (2.9) with the remainder $R_k = O_P(n_*^{-k/2})$. The condition (4.1) is easy to handle. Below, we verify this condition for two classes of statistics: smooth functions of multivariate sample means and $U$–statistics.

In the remaining part of the section we study the first and the second order approximations of asymptotically linear statistics. We shall assume that the linear part $U_1$ is nondegenerate, that is, $s^2 := \text{Var} U_1 > 0$. Note that, by (2.6),

$$s^2 = \tau^2 \sigma_1^2 N/(N-1), \quad \text{where} \quad \tau^2 = Npq, \quad p = n/N, \quad q = 1 - p.$$

Clearly, $n_*/2 \leq \tau^2 \leq n_*$. In Proposition 3 below we formulate sufficient conditions for the asymptotic normality.

**Proposition 3.** Assume that $\tilde{\sigma}$ remains bounded away from zero and $\delta_2 = o(1)$ as $n_*, N \to \infty$. Then $\tilde{\sigma} - s = o(1)$. Suppose, in addition, that (3.3) holds. Then $\tilde{\sigma}^{-1}(T - E T)$, $s^{-1}(T - E T)$ and $(T - E T)/\sigma_{FJ}$ are asymptotically standard normal.

**Proof of Proposition 3.** In view of Theorem 1, the condition $\delta_2 = o(1)$ implies the validity of the short stochastic expansion $T = E T + U_1 + o_P(1)$. We also have $\tilde{\sigma}^2 - s^2 = o(1)$ and, by Proposition 2, $\sigma_{FJ}^2/\tilde{\sigma}^2 = \sigma_{FJ}^2(T/\tilde{\sigma}) = 1 + o_P(1)$. Therefore, the linear part dominates the statistic $T$ and it suffices to prove the asymptotic normality of $s^{-1}U_1$. The asymptotic normality is ensured by (3.3) which (under conditions of the proposition) implies a Lindeberg type Erdős–Rényi condition

$$E g_1^2(X_1) \sigma_1^{-2} \mathbb{I}_{|g_1(X_1)| > \varepsilon \tau \sigma_1} = o(1) \quad \text{as} \quad n_*, N \to \infty,$$

for every $\varepsilon > 0$, see Erdős and Rényi (1959). Note that (3.3) is equivalent to the Erdős–Rényi condition if, in addition, $\tilde{\sigma}$ is bounded as $n_*, N \to \infty$.

Assuming that (4.1) holds, for $k = 2$, we obtain from Theorem 1 the stochastic expansion $T = E T + U_1 + U_2 + O_P(n_*^{-1})$. It suggests that Edgeworth expansions of $T - E T$ and $U_1 + U_2$ should coincide up to the order $O(n_*^{-1})$. Note that $U_1 + U_2$ is a $U$–statistic of degree two. Bloznelis and Götze (2000) showed that an one term asymptotic expansion

$$G(x) = \Phi(x) - \frac{(q - p)\alpha + 3\kappa}{6\tau} \Phi^{(3)}(x)$$
ORTHOLOCAL DECOMPOSITION

approximates the distribution function $P\{U_1 + U_2 \leq x \} \sim \Phi(x)$ with the remainder $O(n^{-1})$. Here $\Phi^{(3)}(x)$ denotes the third derivative of the standard normal distribution function $\Phi(x)$,

$$\alpha = \sigma^{-3} \mathbb{E} g_1^3(X_1), \quad \kappa = \sigma^{-3} \mathbb{E} g_2(X_1, X_2) g_1(X_1) g_1(X_2).$$

Using Theorem 1, one may extend this result to arbitrary symmetric statistics. In particular, in order to construct a one term Edgeworth expansion of $T$ we do not need to evaluate all the summands of (2.1), but (moments of) the first few terms only. A general result formulated in Theorem 2 below provides the bounds $o(n^{-1/2})$ and $O(n^{-1})$ for the error of the expansion

$$\Delta := \sup_x \left| F(x) - G(x) \right|,$$

where $F(x) = P\{T \leq E_T + x \sigma \}$.

Similar bounds hold for

$$\Delta_1 := \sup_x \left| F_1(x) - G(x) \right|,$$

where $F_1(x) = P\{T \leq E_T + x \sigma_1 \tau \}$.

In order to establish the validity of an Edgeworth expansion we need to impose an appropriate smoothness condition. It is the non-lattice condition in the case of the remainder $o(n^{-1/2})$ and it is a Cramér type condition in the case of the remainder $O(n^{-1})$. Either of these conditions will be imposed on the linear part of the statistic.

Given $g : \mathbb{R} \rightarrow \mathbb{C}$ write $\|g\|_{[a,b]} = \sup_{a < |t| < b} |g(t)|$. We shall say that the linear part is asymptotically non–lattice, if for every $\varepsilon > 0$ and every $B > 0$, the characteristic function $\varphi(t) = \mathbb{E} \exp\{it \sigma_1^{-1} g_1(X_1)\}$ of the random variable $\sigma_1^{-1} g_1(X_1)$ satisfies

$$\liminf_{n_*, N \rightarrow \infty} \left\| \varphi \right\|_{[\varepsilon, B]} < 1. \tag{4.2}$$

A more stringent smoothness condition is a Cramér type condition

$$\liminf_{n_*, N \rightarrow \infty} \left\| \varphi \right\|_{[\varepsilon, \tau]} < 1. \tag{4.3}$$

Note that $\tau \rightarrow \infty$ as $n_*, N \rightarrow \infty$. Write

$$\beta_s = \mathbb{E} |n_1^{1/2} g_1(X_1)|^s, \quad \gamma_s = \mathbb{E} |n_2^{3/2} g_2(X_1, X_2)|^s, \quad \zeta_s = \mathbb{E} |n_3^{5/2} g_3(X_1, X_2, X_3)|^s.$$
Theorem 2. Assume that $\bar{\sigma}$ remains bounded away from zero as $N \to \infty$.

(i) Assume that (4.2) holds, $\delta_3 = o(n_*^{-1/2})$ and, for some $\delta > 0$, the moments $\beta_{3+\delta}$ and $\gamma_{2+\delta}$ are bounded as $n_*, N \to \infty$. Then

$$\Delta = o(n_*^{-1/2}) \quad \text{and} \quad \Delta_1 = o(n_*^{-1/2}), \quad \text{as} \quad n_*, N \to \infty.$$ 

(ii) Assume that (4.3) holds, $\delta_4 = O(n_*^{-1})$ and, the moments $\beta_4$, $\gamma_4$, $\zeta_2$ are bounded as $n_*, N \to \infty$. Then

$$\Delta = O(n_*^{-1}) \quad \text{and} \quad \Delta_1 = O(n_*^{-1}) \quad \text{as} \quad n_*, N \to \infty.$$ 

Proof of Theorem 2. Note that either of the conditions (i) and (ii) implies

$$\bar{\sigma}^2 = s^2 + O(n_*^{-1}) = \tau^2 \sigma_1^2 + O(n_*^{-1}).$$ 

Therefore, it suffices to construct bounds for $\Delta_1$.

Let us prove $\Delta_1 = o(n_*^{-1/2})$. In the case of $U$-statistics of degree two (the remainder in (2.9) $R_2 \equiv 0$), this bound is proved in Bloznelis and Götze (1999 a). A passage to the general case can be made by using a Slutzky type argument. Indeed, by (2.9), under condition (i), we have $P\{|R_2| > \varepsilon n_*^{-1/2}\} \leq \varepsilon^{-2} \delta_3 = o(n_*^{-1/2})$, for every $\varepsilon > 0$. Note that $\sup_x |G^{(1)}(x)|$ remains bounded as $n_*, N \to \infty$.

The proof of the bound $\Delta_1 = O(n_*^{-1})$ is rather complex and laborious. It is given in a more technical paper Bloznelis and Götze (1999 b).

Note that if $\bar{\sigma}$ remains bounded away from zero as $n_*, N \to \infty$, then (4.4) implies $\tau \sigma_1/\bar{\sigma} = 1 + O(n_*^{-1})$. Therefore, we can replace $G$ by $G_0$, where

$$G_0(x) = \Phi(x) - \frac{\tau^2}{\bar{\sigma}^2} \frac{(q-p)\alpha_0 + 3 \tau^2 \kappa_0}{6 \bar{\sigma}} \Phi^{(3)}(x),$$

$$\alpha_0 = E g_1^3(X_1), \quad \kappa_0 = E g_2(X_1, X_2) g_1(X_1) g_1(X_2).$$

Corollary. Theorem 2 remains valid if we replace $G$ by $G_0$ in the definition of $\Delta$ and $\Delta_1$.

If $n, N \to \infty$ and $n^2 = o(N)$, the simple random sample model approaches the i.i.d. situation. In this case Theorem 2 and the Corollary agree with the corresponding results of Bentkus, Götze and van Zwet (1997), who constructed second order approximation to symmetric statistics of i.i.d. observations.

In order to construct one term Edgeworth expansion $G$ (respectively $G_0$) one needs to evaluate the parameters $\sigma_1, \alpha, \kappa$ (respectively $\bar{\sigma}, \alpha_0, \kappa_0$). For some classes of statistics it reduces to routine calculations, see examples below. Another possible way is to substitute consistent estimators of these parameters. The consistency of the corresponding jackknife estimators is established in Bloznelis (2000).
Earlier results on Edgeworth expansions for nonlinear asymptotically normal finite population statistics by Babu and Singh (1985), Babu and Bai (1996) apply to statistics which can be approximated by smooth functions of multivariate sample means. Their approach combines linearization and expansions for multivariate sample means. This approach, though conceptually simpler, focuses on particular class of statistics (smooth functions of multivariate sample means). Furthermore, it often requires a bit restrictive Cramér type smoothness condition imposed on the underlying multivariate sample mean rather than on the linear part of the statistic itself. Another approach was used by Kokic and Weber (1990) to prove the validity of one term Edgeworth expansion for finite population $U$-statistic. However, they did not use finite population orthogonal decomposition. In contrast to Theorem 2 all of above mentioned results establish the validity of the expansions under some additional conditions on the sample fraction $p = n/N$.

In what follows we consider two examples: $U$–statistics and smooth functions of sample means.

**Example 1.** $U$–statistics. Given an integer $m$ let $\varphi$ denote a real symmetric function defined on $m$–subsets of the population $X = \{x_1, \ldots, x_N\}$. Define $U$–statistic

$$U = \sum_{1 \leq i_1 < \cdots < i_m \leq n} \varphi(X_{i_1}, \ldots, X_{i_m})$$

based on simple random sample $X_1, \ldots, X_n$ ($n > m$) drawn without replacement from $X$. We shall assume that $E U = 0$ and construct one term Edgeworth expansion $G(x)$. To this aim we evaluate the parameters $\sigma_1$, $\alpha$ and $\kappa$.

Write Hoeffding’s decomposition for symmetric statistic $\varphi(X_1, \ldots, X_m)$,

$$\varphi(X_1, \ldots, X_m) = \sum_{1 \leq k \leq m} \sum_{1 \leq i_1 < \cdots < i_k \leq m} \tilde{g}_k(X_{i_1}, \ldots, X_{i_k}),$$

where symmetric kernels $\tilde{g}_k$ are defined by (2.3). Clearly, every summand $\varphi(X_{i_1}, \ldots, X_{i_m})$ of (4.5) can be written in such form. Substitution of these expressions in (4.5) yields Hoeffding’s decomposition of $U$,

$$U = \sum_{1 \leq k \leq m} \sum_{1 \leq i_1 < \cdots < i_k \leq n} g_k(X_{i_1}, \ldots, X_{i_k}),$$

where $g_k = \left(\frac{n - k}{m - k}\right) \tilde{g}_k$.

Denoting $\sigma_0^2 = E \tilde{g}_1^2(X_1)$ we have $\sigma_1^2 = \left(\frac{n - 1}{m - 1}\right)^2 \sigma_0^2$,

$$\alpha = \sigma_0^{-3} E \tilde{g}_1^3(X_1), \quad \kappa = \frac{(m - 1)n}{n - 1} \frac{q}{\sigma_0^2} E \tilde{g}_2(X_1, X_2)\tilde{g}_1(X_1)\tilde{g}_1(X_2).$$
In order to estimate the moments (of differences) \( \delta_k \), we invoke variance formulas (2.6) and (5.21), see below. A straightforward calculation gives

\[
(4.6) \quad \delta_k \leq c(m)n_s^{k-2}(\text{Var} U_k^2 + \cdots + \text{Var} U_m^2),
\]

where \( c(m) \) denotes a constant which depends only on \( m \). Note that (4.6) implies

\[
n_s^{-(k-1)}\delta_{k+1} \leq c(m)E R_k^2,
\]

where \( R_k \) denotes the remainder of (2.9). That is, for \( U \)-statistics of degree \( m \), the inequality (2.9) is precise (up to the constant \( c(m) \)).

**Example 2. Smooth functions of multivariate sample means.** Assume that \( X \subset \mathbb{R}^k \) and consider the statistic \( T = \sqrt{n/q}(h(\bar{X}) - h(a)) \), where \( h : \mathbb{R}^k \rightarrow \mathbb{R} \). Here \( \bar{X} = n^{-1}(X_1 + \cdots + X_n) \) and \( a = E X \). Assuming that \( h \) is three times differentiable and derivatives are bounded we construct one term Edgeworth expansion and bound \( \delta_4 \). In order to bound \( \delta_4 \) we need one more derivative.

We may assume without loss of generality that \( E X = 0 \).

Denote \( Y_i = h^{(1)}(0)X_i \) and \( Y_{i,j} = h^{(2)}(0)X_iX_j \) and write

\[
\sigma_h^2 = E Y_1^2, \quad \alpha_h = \sigma_h^{-3}E Y_1^3, \quad \kappa_h = \sigma_h^{-3}E Y_1Y_2Y_{1,2}.
\]

Here \( h^{(s)}(y) \) denote the \( s \)-th derivative of \( h \) at the point \( y \in \mathbb{R}^k \). We write \( h^{(s)}(y)z_1 \ldots z_s \) to denote the value of the \( s \)-linear form \( h^{(s)}(y) \) with arguments \( z_1, \ldots, z_s \in \mathbb{R}^k \).

Straightforward, but tedious calculations shows that \( \alpha_h \) and \( q \kappa_h \) provides sufficiently precise approximations to \( \alpha \) and \( \kappa \). Therefore, by Theorem 2,

\[
\Phi(x) - \frac{(q-p)\alpha_h + 3q\kappa_h}{6\tau} \Phi^{(3)}(x)
\]

can be used as one term asymptotic expansion of the distribution function \( P\{T - E T \leq x\sigma_h\} \). The verification of the conditions of Theorem 2 reduces to routine, but cumbersome calculations. We skip most of technical details and focus on the smoothness conditions (4.1) only.

Let \( \|h^{(s)}(y)\| \) denote the smallest \( c > 0 \) such that \( |h^{(s)}(y)z_1 \cdots z_s| \leq c|z_1| \cdots |z_s| \).

Here \( |z_i|^2 = z_{i,1}^2 + \cdots + z_{i,k}^2 \) denotes the Euclidean norm of a vector \( z_i = (z_{i,1}, \ldots, z_{i,k}) \in \mathbb{R}^k \). We say that the \( s \)-th derivative is bounded if \( \|h^{(s)}\|_\infty := \sup_y \|h^{(s)}(y)\| \) is finite.

Assuming that \( \|h^{(j)}\|_\infty \) and \( E |X_1|^2 \) remain bounded as \( n_s, N \rightarrow \infty \) we prove that \( \delta_j(T) = O(n_s^{-1}) \). More precisely, we show that, for every fixed \( j = 1, 2, \ldots, n_s \),

\[
(4.7) \quad \delta_j(T) \leq 2^{j} \frac{N_j}{[N]_j} \|h^{(j)}\|_\infty^2 (E |X_1|^2)^j \frac{n_s^{2j-2}}{q(n^{2j-1})},
\]

where \( [N]_j = N(N-1) \ldots (N-j+1) \). Let \( \varpi_1, \varpi_2, \ldots \) be a sequence of independent random variables uniformly distributed in \([0, 1]\). We assume that the sequence and
the random permutation \((X_1, \ldots, X_N)\) are independent. Given a differentiable function \(f\) we use the mean value formula \(f(x + y) - f(x) = \mathbb{E}_{\mathcal{X}_1} f^{(1)}(x + \mathcal{X}_1 y) y\). Here \(\mathbb{E}_{\mathcal{X}_1}\) denotes the conditional expectation given all the random variables but \(\mathcal{X}_1\). Write \(u_i = n^{-1}(X_i - X'_i)\). By the mean value formula

\[(4.8) \quad \mathbb{D}_j h(\overline{X}) = \mathbb{E}_{\mathcal{X}_1} \ldots \mathbb{E}_{\mathcal{X}_j} h^{(j)}(\overline{X} - (\mathcal{X}_1 u_1 + \cdots + \mathcal{X}_j u_j)) u_1 \cdots u_j,\]

Furthermore, invoking the simple bound \(\mathbb{E} |X_{i_1}|^2 \cdots |X_{i_j}|^2 \leq N^j / [N]_j (\mathbb{E} |X_1|^2)^j\), for \(i_1 < \cdots < i_j\), we obtain \(\mathbb{E} |u_1 \cdots u_j|^2 \leq 2^j N^j / [N]_j n^{-2j} (\mathbb{E} |X_1|^2)^j\). The last inequality in combination with (4.8) implies (4.7).

The smoothness condition on \(h\) can be relaxed. By the law of large numbers, \(\overline{X}\) concentrates around \(a = \mathbb{E} X_1\) with high probability. Therefore, it suffices to impose smoothness conditions on \(h\) in a neighbourhood of \(a\) only.

5. Appendix

We may assume without loss of generality that \(\mathbb{E} T = 0\). Recall that \((X_1, \ldots, X_N)\) denotes random permutation of the ordered set \((x_1, \ldots, x_N)\).

Denote \(\Omega_k = \{1, \ldots, k\}\), for \(k = 1, 2, \ldots\), and \(\Omega = \Omega_N\). Given a statistic \(V = V(X_1, \ldots, X_N)\) write

\[\mathbb{E} (V \mid A) = \mathbb{E} (V \mid X_i, i \in A), \quad A \subset \Omega,\]

and denote \(\mathbb{E} (V \mid \emptyset) = \mathbb{E} V\).

**Proof of (2.3).** Introduce random variables \(Q_A\), for \(A \subset \Omega_n\), with \(|A| \geq 1\). For \(|A| = 1\), we put \(Q_A = \mathbb{E}(T \mid A)\). Let \(n_0\) be the largest integer such that \(2n_0 - 1 \leq N\).

For \(|A| = 2, 3, \ldots, \min\{n_0, n\}\), we define \(Q_A\) recursively as follows. Given \(A \subset \Omega_n\), with \(|A| = k\), write

\[(5.1) \quad Q_A = \mathbb{E}(T \mid A) - d_{k,k-1} \sum_{B \subset A, |B| = k-1} Q_B - \cdots - d_{k,1} \sum_{B \subset A, |B| = 1} Q_B,\]

where the numbers \(d_{k,j}\) are chosen so that for each \(B \subset A\),

\[(5.2) \quad \mathbb{E}(Q_A \mid B) = 0, \quad |B| < |A|\]

A straightforward calculation gives (2.4). In Lemma 1 we extend the identity (5.2) to arbitrary \(B \subset \Omega_N\) satisfying \(|B| < |A|\). Now (5.2) implies that the sums \(\sum_{|B| = i} Q_B\) and \(\sum_{|B| = j} Q_B\) in (5.1) are uncorrelated for \(1 \leq i < j \leq k\). Therefore, (5.1) provides an orthogonal decomposition for the statistic \(\mathbb{E}(T \mid A)\),

\[(5.3) \quad \mathbb{E}(T \mid A) = \sum_{j=1}^k d_{k,j} \sum_{B \subset A, |B| = j} Q_B,\]
where we put $d_{k,k} = 1$.

For $n \leq n_0$ this identity yields the decomposition for $T$

$$T = \mathbb{E}(T|\Omega_n) = \sum_{B \subset \Omega_n, |B| \geq 1} T_B, \quad T_B = d_{n,|B|} Q_B,$$

where for every $B \subset \Omega_n$ and $C \subset \Omega_N$ we have almost surely

$$\mathbb{E}(T_B|C) = 0, \quad \text{for } |C| < |B|.$$

Denoting

$$g_k(x_1, \ldots, x_k) = \mathbb{E}(T_{\Omega_k} | X_1 = x_1, \ldots, X_k = x_k), \quad k = 1, 2, \ldots, n,$$

we obtain (2.1) from (5.4) and (2.2) from (5.5).

Now assume that $n > n_0$. For $k = n_0 + 1, \ldots, n$ we show that (5.3) remains valid if we choose $d_{k,j} = 0$, for $j = N - k + 1, \ldots, k$. Let $Q_A$ with $|A| = k$ be defined by (5.1). A calculation shows that if for $j = 1, \ldots, N - k$ the numbers $d_{k,j}$, are given by (2.4) and $d_{k,j} = 0$ for $j > N - k$ then (5.2) holds for every $B \subset A$ with $|B| \leq N - k$. Proceeding as in proof of (5.8) below one can show that (5.2) extends to arbitrary $B \subset \Omega_N$ such that $|B| \leq N - k$. In particular, for $A = \Omega_k$ and $B = \Omega_N \setminus \Omega_k$ we have $\mathbb{E}(Q_A|B) = 0$ almost surely. Since $\mathbb{E}(Q_A|B) = Q_A$, we obtain $Q_A = 0$ almost surely thus proving (5.3). In the case where $A = \Omega_n$ the identity (5.3) provides the orthogonal decomposition for $T$,

$$T = \mathbb{E}(T|\Omega_n) = \sum_{j=1}^{N-n} \sum_{B \subset \Omega_n, |B| = j} T_B, \quad T_B = d_{n,|B|} Q_B,$$

where $Q_B$ is given by (5.1) and satisfy (5.2) and (5.5). Finally, invoking a simple combinatoric calculation we derive (2.3) from (5.1) and (5.4), (5.6).

Before to formulate Lemmas 1 and 2 we introduce some notation. Define the random variable $T_A$ for arbitrary $A = \{i_1, \ldots, i_r\} \subset \Omega$, with cardinality $r \leq n$, by putting $T_A = g_r(X_{i_1}, \ldots, X_{i_r})$. Let us write also $T_0 = 0$. Note that $T_A$ is a centered symmetric statistic of observations $X_i$, $i \in A$. Two random variables $T_A$ and $T_B$ are identically distributed if $|A| = |B|$. The difference operation $D_i$ can be applied to $T_A$ provided that $i' = n + i \notin A$. We write $D^{i}T_A = T_A - T_{A\{i\}}$ if $i \notin A$ and put $D^{i}T_A = 0$ otherwise. Here $A(\{i\}) = (A \setminus \{i\}) \cup \{i'\}$. A higher order differences $D_i = D_i^* \ldots D_1$ are defined recursively: $D_2T_A = D^2T_A = D^2T_A(\{1\})$, etc. We shall apply these differences to $T_A$, with $A \in \Omega_n$. Note that $D_i T_A = 0$, whenever $\Omega_i \notin A$. If $\Omega_i \subset A$, we can write $A = \Omega_i \cup B$, for some $B \subset \Omega_n \setminus \Omega_i$. In this case we have

$$D_i T_{\Omega_i \cup B} = \sum_{C \subset \Omega_i} (-1)^{|C|} T_{\Omega_i(C) \cup B},$$

$$\Omega_i(C) = (\Omega_i \setminus C) \cup C', \quad C' = \{l': l \in C\}, \quad l' = l + n.$$
Here we write also $\Omega_i(\emptyset) = \Omega_i$.

Given $A, B \in \Omega$, with $|A \cap B| = k$ and $|A| = |B| = j$, $j \leq n$, denote

$$\sigma_j^2 = \mathbf{E} T_A^2, \quad s_{j,k} = \mathbf{E} T_A T_B.$$ 

If, in addition, $A, B \subset \Omega_n \setminus \Omega_i$ we write

$$\sigma_{i,j}^2 = \mathbf{E} (\mathbb{D}_i T_{\Omega_i \cup A})^2, \quad s_{i,j,k} = \mathbf{E} \mathbb{D}_i T_{\Omega_i \cup A} \mathbb{D}_i T_{\Omega_i \cup B}.$$ 

Put $\sigma_{0,j}^2 = \sigma_j^2$ and $s_{0,j,k} = s_{j,k}$.

**Lemma 1.** The following identities hold

\begin{align*}
(5.8) \quad & \mathbf{E} (T_G | H) = 0, \quad \text{for every } G, H \subset \Omega \quad \text{with } |H| < |G|, \\
(5.9) \quad & s_{j,k} = \frac{(-1)^{j-k}}{N-j} \sigma_j^2, \quad 0 \leq k \leq j \leq n_0, \\
(5.10) \quad & s_{i,j,k} = \frac{(-1)^{j-k}}{N-j-2i} \sigma_{i,i+j}^2, \quad 0 \leq k \leq j \leq n_0 - i, \\
(5.11) \quad & \sigma_{i,j}^2 = \frac{N-j+1}{N-j-i+1} 2^i \sigma_j^2, \quad i \leq j \leq n_0.
\end{align*}

**Proof of Lemma 1.** We start with an auxiliary identity (5.12). Fix $C, D \subset \Omega$ such that $1 \leq |C| \leq |D|$ and $|C \setminus D| = 1$. Denote $C_1 = C \cap D$. We have

\begin{equation}
\mathbf{E} (T_C | D) = \frac{1}{N-|D|} \sum_{i \in \Omega \setminus D} T_{\{i\} \cup C_1} = \frac{-1}{N-|D|} \sum_{i \in D \setminus C} T_{\{i\} \cup C_1},
\end{equation}

since, $(\Omega \setminus D) \cup (D \setminus C) = \Omega \setminus C_1$ and, by (5.5),

$$\sum_{i \in \Omega \setminus C_1} T_{\{i\} \cup C_1} = (N - |C_1|) \mathbf{E} (T_C | C_1) = 0.$$

Let us prove (5.8). For $H \subset G \subset \Omega_n$, (5.8) follows from (5.5). By symmetry, it still holds for $H \subset G \subset \Omega$. For $|H \setminus G| = k$, we prove (5.8) by induction. Assume that (5.8) holds for every $k \leq r$. Given $G, H \subset \Omega$, with $|H \setminus G| = r+1$, fix $a \in G \setminus H$ and denote $G_a = G \setminus \{a\}$. Write $\mathbf{E} (T_G | H) = \mathbf{E} (V_a | H)$, where $V_a = \mathbf{E} (T_G | G_a \cup H)$. An application of (5.12) to $V_a$ gives $\mathbf{E} (V_a | H) = 0$, by induction hypothesis, with $k = r$. Hence, $\mathbf{E} (T_G | H) = 0$ and we obtain (5.8), with $k = r + 1$. 
Let us prove (5.9). Given $A, B \subset \Omega$, with $|A| = |B| = j \geq 1$ and $|A \cap B| = k < j$, fix $i_a \in A \setminus B$ and denote $A_1 = A \setminus \{i_a\}$. An application of (5.12) gives

$$
 s_{j,k} = \mathbf{E} T_B \mathbf{E} (T_A | A_1 \cup B) = \frac{-1}{N - (2j - k - 1)} \sum_{i \in B \setminus A} \mathbf{E} T_B T_{\{i\} \cup A_1}
$$

(5.13)

$$
 = \frac{(-1)(j - k)}{N - (2j - k - 1)} s_{j,k+1},
$$

where the last identity follows by symmetry. Applying (5.13) several times, for increasing $k$, we obtain (5.9).

Let us prove (5.10). Let $A, B$ be as above and assume in addition that $A, B \subset \Omega_n \setminus \Omega_i$. Fix $i_a \in A \setminus B$ and $i_b \in B \setminus A$. Denote $B_1 = B \setminus \{i_b\}$ and $B_2 = B_1 \cup \{i_a\}$. It follows from (5.7) that

$$
 s_{i,j,k} = \sum_{C \subset \Omega_i} (-1)^{|C|} \mathbf{E} \mathcal{D}_i T_{\Omega_i \cup A} h_C, \quad h_C = T_{\Omega_i(C) \cup B},
$$

(5.14)

Write $H = A \cup \Omega_i \cup \Omega'_i \cup B_1$, where $\Omega'_i = \{1', \ldots, i'\}$. By (5.12),

$$
 \mathbf{E} (h_C | H) = \frac{-1}{N - |H|} M, \quad M = \sum_{r \in H \setminus (\Omega_i(C) \cup B_1)} T_{\Omega_i(C) \cup B_1 \cup \{r\}}.
$$

Split $M = K_C + L_C$,

$$
 K_C = \sum_{r \in A \setminus B} T_{\Omega_i(C) \cup B_1 \cup \{r\}}, \quad L_C = \sum_{r \in (\Omega_i(C) \cup \Omega'_i) \setminus \Omega_i(C)} T_{\Omega_i(C) \cup B_1 \cup \{r\}}
$$

and substitute the expression $\mathbf{E} (h_C | H) = -(N - |H|)^{-1} (K_C + L_C)$, in (5.14) to get

$$
 s_{i,j,k} = \sum_{C \subset \Omega_i} (-1)^{|C|} \mathbf{E} \mathcal{D}_i T_{\Omega_i \cup A} \mathbf{E} (h_C | H) = \frac{-1}{N - |H|} (S_K + S_L),
$$

(5.15)

$$
 S_K = \sum_{C \subset \Omega_i} (-1)^{|C|} \mathbf{E} \mathcal{D}_i T_{\Omega_i \cup A} K_C, \quad S_L = \sum_{C \subset \Omega_i} (-1)^{|C|} \mathbf{E} \mathcal{D}_i T_{\Omega_i \cup A} L_C.
$$

We shall show below that $S_L = 0$. Now consider $S_K$. By symmetry,

$$
 \mathbf{E} \mathcal{D}_i T_{\Omega_i \cup A} K_C = |A \setminus B| \mathbf{E} \mathcal{D}_i T_{\Omega_i \cup A} T_{\Omega_i(C) \cup B_2}.
$$

Therefore, $S_K = (j - k)S$, where, by (5.7),

$$
 S = \mathbf{E} \mathcal{D}_i T_{\Omega_i \cup A} \sum_{C \subset \Omega_i} (-1)^{|C|} T_{\Omega_i(C) \cup B_2} = \mathbf{E} \mathcal{D}_i T_{\Omega_i \cup A} \mathcal{D}_i T_{\Omega_i \cup B_2}.
$$
We obtain $S_K = (j - k)s_{i,j,k+1}$. Finally, by (5.15) and the identity $S_L = 0$, we have

$$s_{i,j,k} = \frac{(-1)}{N - |H|} S_K = \frac{(-1)(j - k)}{N - (2j + 2k - k - 1)} s_{i,j,k+1}.$$  

Applying this identity several times, for decreasing $k$, we obtain (5.10). It remains to prove $S_L = 0$. To this aim we shall show that almost surely

$$\sum_{C \subseteq \Omega_i} (-1)^{|C|} L_C = \sum_{C \subseteq \Omega_i} (-1)^{|C|} \sum_{r \in \Omega^*_i(C)} T_{\Omega_i(C) \cup B_1 \cup \{r\}} = 0.$$  

Here $\Omega^*_i(C) = (\Omega_i \cup \Omega^*_i) \setminus \Omega_i(C)$. Note that for any fixed $C \subseteq \Omega_i$ and $j_1 \in \Omega^*_i(C)$ there exists a unique pair $D, j_2$, with $D \neq C$, where $D \subseteq \Omega_i$ and $j_2 \in \Omega^*_i(D)$ such that

$$\Omega_i(C) \cup \{j_1\} = \Omega_i(D) \cup \{j_2\}.$$  

Namely, if $j_1 \in \Omega^*_i$ then $j_1 = j'$ for some $j \in \Omega_i$ and in this case $D = C \cup \{j\}$. If $j_1 \in \Omega_i$ then necessarily $j_1 \in C$ and in this case $D = C \setminus \{j_1\}$. In both cases we have $|C| - |D| = 1$ and therefore, $(-1)^{|C|} + (-1)^{|D|} = 0$. Hence, for every random variable $T_{\Omega_i(C) \cup B_1 \cup \{j\}}$ of the sum (5.17) there exists a unique counterpart $T_{\Omega_i(D) \cup B_1 \cup \{j\}}$ (in the same sum) satisfying (5.18). Clearly, we have

$$(-1)^{|C|} T_{\Omega_i(C) \cup B_1 \cup \{j_1\}} + (-1)^{|D|} T_{\Omega_i(D) \cup B_1 \cup \{j_2\}} = 0$$

and thus, (5.17) follows.

Let us prove (5.11). Fix $A \subseteq \Omega \setminus \Omega_i$ with $|A| = j - i$. We have

$$\sigma^2_{i,j} = \mathbf{E} \left( \mathbb{D}_i T_{\Omega_i \cup A} \right)^2 = \mathbf{E} \left( \mathbb{D}_{i-1} T_{\Omega_i \cup A} - \mathbb{D}_{i-1} T_{\Omega_i \cup \{j\} \cup A} \right)^2$$

$$= \mathbf{E} \left( \mathbb{D}_{i-1} T_{\Omega_i \cup A} \right)^2 + \mathbf{E} \left( \mathbb{D}_{i-1} T_{\Omega_i \cup \{j\} \cup A} \right)^2 - 2 \mathbf{E} \mathbb{D}_{i-1} T_{\Omega_i \cup A} \mathbb{D}_{i-1} T_{\Omega_i \cup \{j\} \cup A}$$

$$= 2 \sigma^2_{i-1,j} - 2 s_{i-1,j-i+1,j-i} = 2 \left( 1 + \frac{1}{N - (j + i - 1)} \right) \sigma^2_{i-1,j}.$$  

In the last step we used (5.16). Applying this identity several times, for decreasing $k$, we obtain (5.11) thus completing the proof of the lemma.

We shall consider statistics of the form: $V = \sum_{B \subseteq \mathcal{H}} T_B$, where $\mathcal{H}$ denotes some class of subsets $B$ of $\Omega$ with $|B| \leq n$. Denote $U_j(V) = \sum_{B \subseteq \mathcal{H}, |B| = j} T_B$ and write $e_j(V) = \sigma_j^{-2} \mathbf{V} U_j(V)$, for $\sigma_j^2 > 0$. Otherwise put $e_j(V) = 0$. By (5.8), random variables $U_r(V)$ and $U_k(V)$ are uncorrelated, for $r \neq k$. Therefore,

$$\mathbf{V} V = \mathbf{V} U_1(V) + \cdots + \mathbf{V} U_n(V) = e_1(V) \sigma_1^2 + \cdots + e_n(V) \sigma_n^2$$

In what follows we use the formula

$$\sum_{v=0}^{\min\{s,k\}} (-1)^v \binom{s}{v} \binom{k}{v} \binom{u}{v}^{-1} = \binom{u-s}{k} \binom{u}{k}^{-1},$$

where the integers $s, t, u \geq 0$, see, e.g., Zhao and Chen (1990).

Write $r_{i,j} = \binom{N-n-i}{j-i} \binom{N-i-j}{j-i}^{-1}$.
Lemma 2. The formulas (2.6) holds true. For every $1 \leq i \leq j \leq n_*$, we have

\begin{align*}
(5.21) \quad \text{Var } U_j(\mathbb{D}_i T) &= \binom{n-i}{j-i} r_{i,j} \sigma_{i,j}^2 = \left( \frac{n-i}{j-i} \right) r_{i,j} \frac{N-j+1}{N-i-j+1} 2^i \sigma_j^2, \\
(5.22) \quad \text{Var } U_j(T) &\leq (n_*/2)^i \text{Var } U_j(\mathbb{D}_i T).
\end{align*}

Proof of Lemma 2. Let us prove the first part of (2.6). By symmetry,

\begin{align*}
(5.23) \quad \text{Var } U_j(T) &= \binom{n}{j} \mathbf{E} \Omega_j U_j(T) \quad \text{and} \quad \mathbf{E} \Omega_j U_j(T) = \sum_{v=0}^{n-j} m_v s_{j,j-v},
\end{align*}

where $m_v$ denotes the number of subsets $B \subset \Omega_n$, with $|B| = j$, satisfying $|B \cap (\Omega_n \setminus \Omega_j)| = v$. Clearly, $m_v = \binom{n-j}{j-v}$. Therefore,

$$
\mathbf{E} \Omega_j U_j(T) = \sum_{v=0}^{v_0} \binom{n-j}{v} \binom{j}{v} s_{j,j-v}, \quad v_0 := \min\{n-j,j\}.
$$

Invoking (5.9) and then using (5.20) we obtain $\mathbf{E} \Omega_j U_j(T) = r_{0,j} \sigma_j^2$. This identity in combination with (5.23) gives the first part of (2.6). The second part is trivial, cf (5.19).

Let us prove (5.21). We have

$$
U_j(\mathbb{D}_i T) = \sum_{A \subset \Omega_n \setminus \Omega_j, |A|=j-i} \mathbb{D}_i T_{\Omega_j \cup A}, \quad i \leq j \leq n.
$$

By symmetry,

$$
\text{Var } U_j(\mathbb{D}_i T) = \binom{n-i}{j-i} \mathbf{E} \mathbb{D}_i T_{\Omega_j} U_j(\mathbb{D}_i T),
$$

$$
\mathbf{E} \mathbb{D}_i T_{\Omega_j} U_j(\mathbb{D}_i T) = \sum_{u=0}^{\min\{n-j,j-i\}} \binom{n-j}{u} \binom{j-i}{j-i-u} s_{i,j-i,j-i-u}.
$$

Invoking (5.10) and then using (5.20) we obtain $\mathbf{E} \mathbb{D}_i T_{\Omega_j} U_j(\mathbb{D}_i T) = r_{i,j} \sigma_{i,j}^2$, thus, proving the first identity of (5.21). The second one follows from (5.11).

The inequality (5.22) is a simple consequence of the identity

$$
\frac{\text{Var } U_j(\mathbb{D}_i T)}{\text{Var } U_j(T)} = 2^i \frac{[j]_i [N-j+1]_i}{[n]_i [N-n]_i},
$$

which follows from (2.6) and (5.21).
**Proof of Theorem 1.** Combining (2.7) and (5.22) we obtain

\[ E R_k^2 = \text{Var} U_{k+1}(T) + \cdots + \text{Var} U_{n_\ast}(T) \]

\[ \leq \left( \frac{n_\ast}{2} \right)^{k+1} \left( \text{Var} U_{k+1}({\mathcal D}_{k+1}T) + \cdots + \text{Var} U_{n_\ast}({\mathcal D}_{k+1}T) \right) \]

\[ = n_\ast^{1-k} 2^{-1-k} \delta_{k+1}. \]

**Proof of (3.1).** Using the identity \( \sigma_j^2 = \sum_{i=1}^{n+1} T_i^2 - (n+1)T^2 \) it is easy to show that (3.1) is equivalent to the inequality \((n+1-q^{-1})E T^2 \geq (n+1)E T^2\). In order to prove this inequality it suffices to show that for every \( j = 1, \ldots, n_\ast, \)

\[ (5.24) \quad (n+1-q^{-1})\text{Var} U_j(T) \geq (n+1)^{-1}\text{Var} U_j(H), \quad H = (n+1)\overline{T}. \]

Let us evaluate \(\text{Var} U_j(H)\). An application of (2.1) to \(T_1, \ldots, T_{n+1}\) gives

\[ H = \sum_{j=1}^{n_\ast} (n+1-j)W_j, \quad W_j = \sum_{B \subseteq \Omega_{n+1}, |B|=j} T_B. \]

Proceeding as in proof of (5.23) we obtain

\[ E W_j^2 = \binom{n+1}{j} \binom{N-n-1}{j} \binom{N-j}{j}^{-1} \sigma_j^2. \]

Therefore, we have an explicit formula for \(\text{Var} U_j(H) = (n+1-j)^2 E W_j^2\). Invoking (2.6) we obtain an explicit formula for the left-hand side of (5.24) as well. Now a simple arithmetics proves (5.24).

**Proof of Proposition 2.** Under condition (i) we have \( s^2 - \bar{s}^2 = o(1) \) as \( n_\ast, N \to \infty \). In particular, \( s^2 = O(1) \). Let \( V^2 = \sigma_j^2(U_1(T)) \) denote the jackknife variance estimator of \( U_1(T) \), the linear part of \( T \). In order to prove (3.2) it suffices to show that as \( n_\ast, N \to \infty \)

\[ q(\sigma_j^2 - V^2) = o_P(1) \quad \text{and} \quad qV^2 - s^2 = o_P(1). \]

The first relation is implied by the smoothness condition \( \delta_2 = o(1) \). The second relations follows by the (weak) law of large numbers (use (3.3) and the fact that \( s^2 = O(1) \)).
